# Configure Jupyter to display the assigned value after an assignment
%config InteractiveShell.ast_node_interactivity='last_expr_or_assign'

# import functions from the modsim.py module
from modsim import *
```

## Code

Here's the code from the previous notebook that we'll need.

```
In [2]: def make_system(beta, gamma):
    """Make a system object for the SIR model.

    beta: contact rate in days
    gamma: recovery rate in days

    returns: System object
    """
    init = State(S=89, I=1, R=0)
    init /= sum(init)

    t0 = 0
    t_end = 7 * 14

    return System(init=init, t0=t0, t_end=t_end,
                  beta=beta, gamma=gamma)
```

```
In [3]: def update_func(state, t, system):
    """Update the SIR model.

    state: State with variables S, I, R
    t: time step
    system: System with beta and gamma

    returns: State object
    """
    s, i, r = state

    infected = system.beta * i * s
    recovered = system.gamma * i

    s -= infected
    i += infected - recovered
```

```
r += recovered

return State(S=s, I=i, R=r)
```

```
In [4]: def run_simulation(system, update_func):
    """Runs a simulation of the system.

    system: System object
    update_func: function that updates state

    returns: TimeFrame
    """
    frame = TimeFrame(columns=system.init.index)
    frame.row[system.t0] = system.init

    for t in linrange(system.t0, system.t_end):
        frame.row[t+1] = update_func(frame.row[t], t, system)

    return frame
```

## Metrics

Given the results, we can compute metrics that quantify whatever we are interested in, like the total number of sick students, for example.

```
In [5]: def calc_total_infected(results):
    """Fraction of population infected during the simulation.

    results: DataFrame with columns S, I, R

    returns: fraction of population
    """
    return get_first_value(results.S) - get_last_value(results.S)
```

Here's an example.]

```
In [6]: beta = 0.333
gamma = 0.25
system = make_system(beta, gamma)

results = run_simulation(system, update_func)
print(beta, gamma, calc_total_infected(results))
```

0.333 0.25 0.46716293183605073

**Exercise:** Write functions that take a `TimeFrame` object as a parameter and compute the other metrics mentioned in the book:

1. The fraction of students who are sick at the peak of the outbreak.
2. The day the outbreak peaks.
3. The fraction of students who are sick at the end of the semester.

Note: Not all of these functions require the `System` object, but when you write a set of related functions, it is often convenient if they all take the same parameters.

Hint: If you have a `TimeSeries` called `I`, you can compute the largest value of the series like this:

```
I.max()
```

And the index of the largest value like this:

```
I.idxmax()
```

You can read about these functions in the [Series documentation](#).

```
In [7]: # Solution goes here
```

```
def get_sick_at_peak(results):
    return results.I.max()

get_sick_at_peak(results)
```

```
Out[7]: 0.043536202687592354
```

```
In [8]: # Solution goes here
```

```
def day_at_peak(results):

    return results.I.idxmax()

day_at_peak(results)
```

```
Out[8]: 30
```

```
In [9]: # Solution goes here
```

```
def get_sick_at_end(results):
    return get_last_value(results.I)

get_sick_at_end(results)
```

```
Out[9]: 0.0006741943156034474
```

## What if?

We can use this model to evaluate "what if" scenarios. For example, this function models the effect of immunization by moving some fraction of the population from S to R before the simulation starts.

```
In [10]: def add_immunization(system, fraction):
    """Immunize a fraction of the population.

    Moves the given fraction from S to R.

    system: System object
    fraction: number from 0 to 1
    """
```

```
    system.init.S -= fraction
    system.init.R += fraction
```

Let's start again with the system we used in the previous sections.

```
In [11]: tc = 3      # time between contacts in days
          tr = 4      # recovery time in days

          beta = 1 / tc      # contact rate in per day
          gamma = 1 / tr      # recovery rate in per day

          system = make_system(beta, gamma)
```

```
Out[11]:
```

	values
init	S 0.988889 I 0.011111 R 0.000000 dtype...
t0	0
t_end	98
beta	0.333333
gamma	0.25

And run the model without immunization.

```
In [12]: results = run_simulation(system, update_func)
          calc_total_infected(results)
```

```
Out[12]: 0.468320811028781
```

Now with 10% immunization.

```
In [13]: system2 = make_system(beta, gamma)
          add_immunization(system2, 0.1)
          results2 = run_simulation(system2, update_func)
          calc_total_infected(results2)
```

```
Out[13]: 0.30650802853979753
```

10% immunization leads to a drop in infections of 16 percentage points.

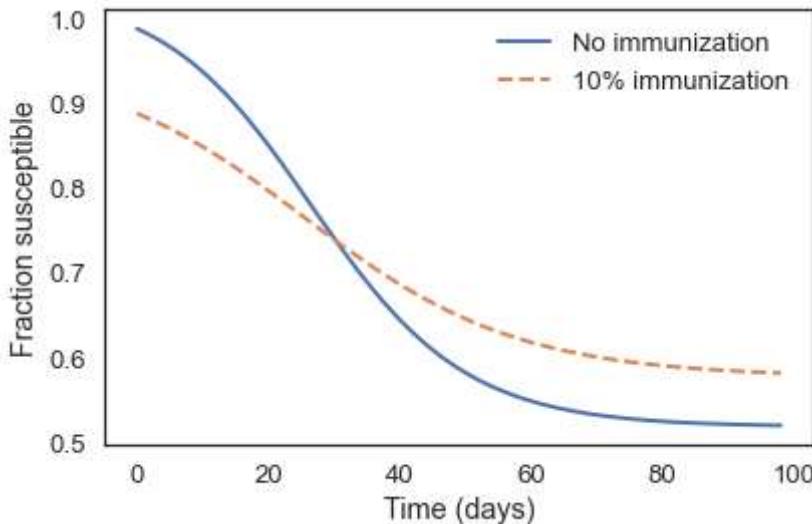

Here's what the time series looks like for S, with and without immunization.

```
In [14]: plot(results.S, '-', label='No immunization')
          plot(results2.S, '--', label='10% immunization')

          decorate(xlabel='Time (days)',
                    ylabel='Fraction susceptible')

          savefig('figs/chap12-fig01.pdf')
```

```
Saving figure to file figs/chap12-fig01.pdf
```

Now we can sweep through a range of values for the fraction of the population who are immunized.

```
In [15]: immunize_array = linspace(0, 1, 11)
for fraction in immunize_array:
    system = make_system(beta, gamma)
    add_immunization(system, fraction)
    results = run_simulation(system, update_func)
    print(fraction, calc_total_infected(results))
```

```
0.0 0.468320811028781
0.1 0.30650802853979753
0.2 0.16136545700638427
0.3000000000000004 0.0728155898425179

0.9 0.0014815326722661948
1.0 -0.00016121210941239666
```

This function does the same thing and stores the results in a `Sweep` object.

```
In [16]: def sweep_im immunity(immunize_array):
    """Sweeps a range of values for immunity.

    immunize_array: array of fraction immunized

    returns: Sweep object
    """
    sweep = SweepSeries()

    for fraction in immunize_array:
        system = make_system(beta, gamma)
        add_immunization(system, fraction)
        results = run_simulation(system, update_func)
        sweep[fraction] = calc_total_infected(results)

    return sweep
```

Here's how we run it.

```
In [17]: immunize_array = linspace(0, 1, 21)
```

```
infected_sweep = sweep_immunity(immunize_array)
```

Out[17]:

	values
<b>0.00</b>	0.468321
<b>0.05</b>	0.387288

<b>0.90</b>	0.001482
<b>0.95</b>	0.000603
<b>1.00</b>	-0.000161

And here's what the results look like.

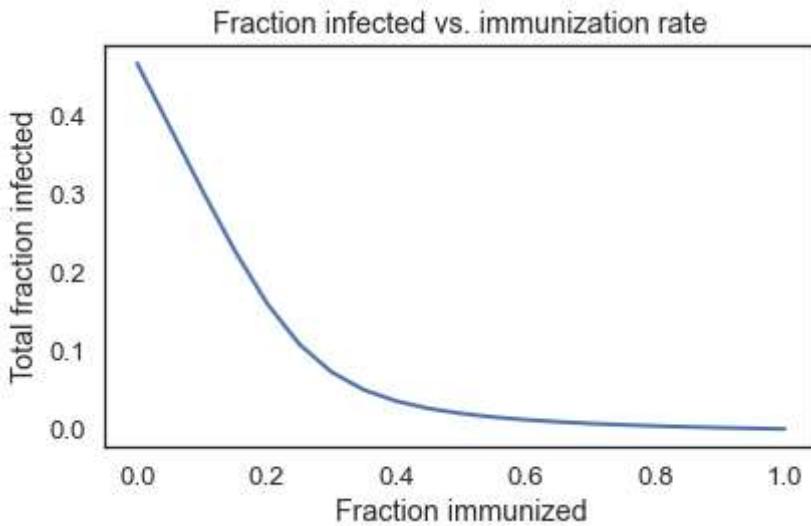

In [18]:

```
plot(infected_sweep)

decorate(xlabel='Fraction immunized',
         ylabel='Total fraction infected',
         title='Fraction infected vs. immunization rate',
         legend=False)

savefig('figs/chap12-fig02.pdf')
```

Saving figure to file figs/chap12-fig02.pdf

If 40% of the population is immunized, less than 4% of the population gets sick.

## Logistic function

To model the effect of a hand-washing campaign, I'll use a [generalized logistic function](#) (GLF), which is a convenient function for modeling curves that have a generally sigmoid shape. The parameters of the GLF correspond to various features of the curve in a way that makes it easy to find a function that has the shape you want, based on data or background information about the scenario.

```
In [19]: def logistic(x, A=0, B=1, C=1, M=0, K=1, Q=1, nu=1):
    """Computes the generalize logistic function.

    A: controls the lower bound
    B: controls the steepness of the transition
    C: not all that useful, AFAIK
    M: controls the location of the transition
    K: controls the upper bound
    Q: shift the transition left or right
    nu: affects the symmetry of the transition

    returns: float or array
    """
    exponent = -B * (x - M)
    denom = C + Q * exp(exponent)
    return A + (K-A) / denom ** (1/nu)
```

The following array represents the range of possible spending.

```
In [20]: spending = linspace(0, 1200, 21)
```

```
Out[20]: array([ 0.,  60., 120., 180., 240., 300., 360., 420., 480.,
   540., 600., 660., 720., 780., 840., 900., 960., 1020.,
 1080., 1140., 1200.])
```

`compute_factor` computes the reduction in `beta` for a given level of campaign spending.

`M` is chosen so the transition happens around \$500.

`K` is the maximum reduction in `beta`, 20%.

$B$  is chosen by trial and error to yield a curve that seems feasible.

```
In [21]: def compute_factor(spending):
    """Reduction factor as a function of spending.

    spending: dollars from 0 to 1200

    returns: fractional reduction in beta
    """
    return logistic(spending, M=500, K=0.2, B=0.01)
```

Here's what it looks like.

```
In [22]: percent_reduction = compute_factor(spending) * 100

plot(spending, percent_reduction)

decorate(xlabel='Hand-washing campaign spending (USD)',
        ylabel='Percent reduction in infection rate',
        title='Effect of hand washing on infection rate',
        legend=False)
```

**Exercise:** Modify the parameters  $M$ ,  $K$ , and  $B$ , and see what effect they have on the shape of the curve. Read about the [generalized logistic function on Wikipedia](#). Modify the other parameters and see what effect they have.

```
In [23]: # Solution goes here

def compute_factor(spending):
    """Reduction factor as a function of spending.

    spending: dollars from 0 to 1200

    returns: fractional reduction in beta
    """
    return logistic(spending, M=100, K=0.2, B=0.01)
percent_reduction = compute_factor(spending) * 100

plot(spending, percent_reduction)

decorate(xlabel='Hand-washing campaign spending (USD)',
```

```
ylabel='Percent reduction in infection rate',
title='Effect of hand washing on infection rate',
legend=False)
```

Notice the transition occurring at 100.

Now let's modify K from .2 to .5

```
In [24]: # Solution goes here

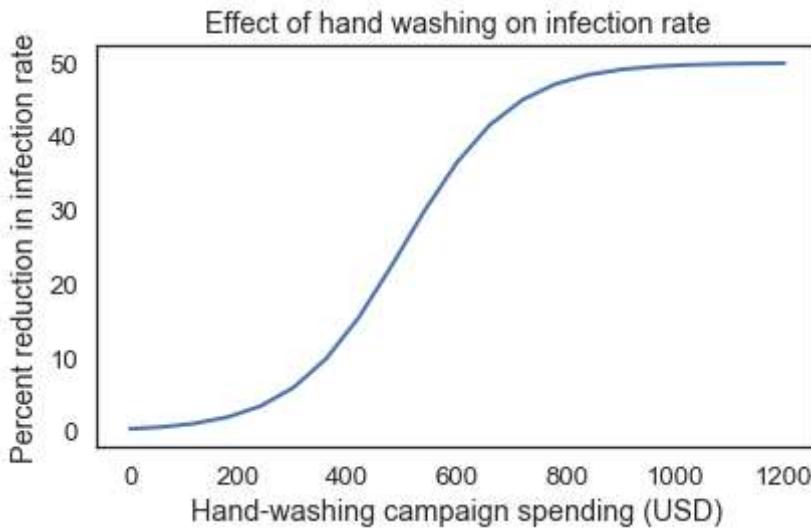

def compute_factor(spending):
    """Reduction factor as a function of spending.

    spending: dollars from 0 to 1200

    returns: fractional reduction in beta
    """
    return logistic(spending, M=500, K=0.5, B=0.01)
percent_reduction = compute_factor(spending) * 100

plot(spending, percent_reduction)

decorate(xlabel='Hand-washing campaign spending (USD)',
        ylabel='Percent reduction in infection rate',
        title='Effect of hand washing on infection rate',
        legend=False)
```

This increase in K increases the percent reduction rate from .2 to .5 on the y-axis. Now let's modify beta from .01 to .1

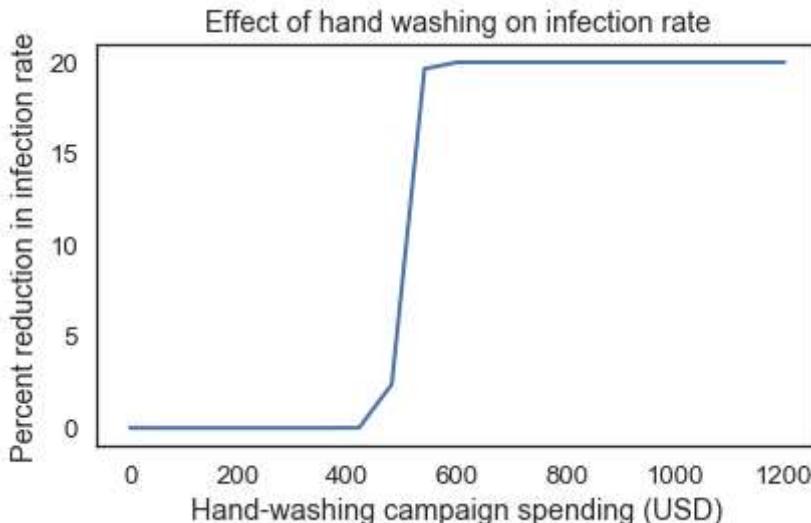

```
In [25]: # Solution goes here

def compute_factor(spending):
    """Reduction factor as a function of spending.

    spending: dollars from 0 to 1200

    returns: fractional reduction in beta
    """
    return logistic(spending, M=500, K=0.2, B=0.1)
percent_reduction = compute_factor(spending) * 100
plot(spending, percent_reduction)

decorate(xlabel='Hand-washing campaign spending (USD)',
        ylabel='Percent reduction in infection rate',
        title='Effect of hand washing on infection rate',
        legend=False)
```

Modifying beta from .01 to .1 steepens the curve at the transition.

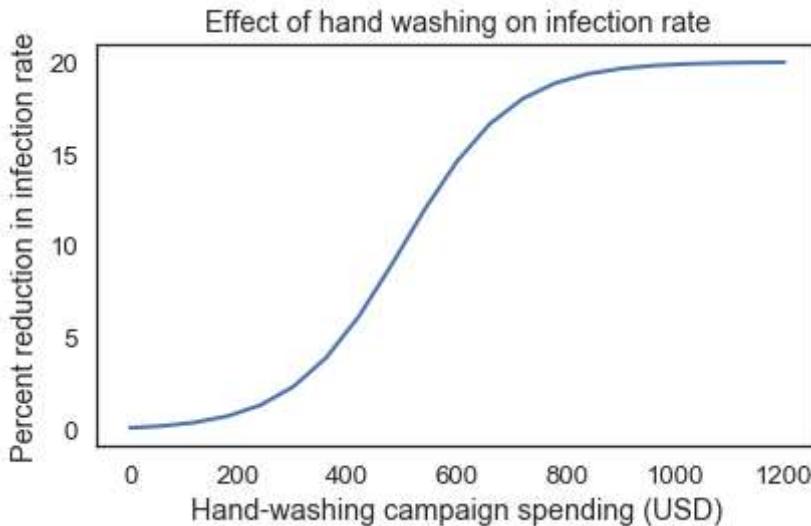

```
In [26]: # back to original
# Solution goes here

def compute_factor(spending):
    """Reduction factor as a function of spending.

    spending: dollars from 0 to 1200

    returns: fractional reduction in beta
    """
    return logistic(spending, M=500, K=0.2, B=0.01)
percent_reduction = compute_factor(spending) * 100
plot(spending, percent_reduction)

decorate(xlabel='Hand-washing campaign spending (USD)',
        ylabel='Percent reduction in infection rate',
        title='Effect of hand washing on infection rate',
        legend=False)
```

## Hand washing

Now we can model the effect of a hand-washing campaign by modifying `beta`

```
In [27]: def add_hand_washing(system, spending):
    """Modifies system to model the effect of hand washing.

    system: System object
    spending: campaign spending in USD
    """
    factor = compute_factor(spending)
    system.beta *= (1 - factor)
```

Let's start with the same values of `beta` and `gamma` we've been using.

```
In [28]: tc = 3      # time between contacts in days
tr = 4        # recovery time in days

beta = 1 / tc      # contact rate in per day
gamma = 1 / tr     # recovery rate in per day

beta, gamma
```

```
Out[28]: (0.3333333333333333, 0.25)
```

Now we can sweep different levels of campaign spending.

```
In [29]: spending_array = linspace(0, 1200, 13)
```

```
for spending in spending_array:  
    system = make_system(beta, gamma)  
    add_hand_washing(system, spending)  
    results = run_simulation(system, update_func)  
    print(spending, system.beta, calc_total_infected(results))
```

```
0.0 0.3328871432717143 0.4667702312363652  
100.0 0.3321342526691939 0.46414165040064037

1200.0 0.26672740341296003 0.1875955039953746
```

Here's a function that sweeps a range of spending and stores the results in a `SweepSeries`.

```
In [30]: def sweep_hand_washing(spending_array):  
    """Run simulations with a range of spending.  
  
    spending_array: array of dollars from 0 to 1200  
  
    returns: Sweep object  
    """  
    sweep = SweepSeries()  
  
    for spending in spending_array:  
        system = make_system(beta, gamma)  
        add_hand_washing(system, spending)  
        results = run_simulation(system, update_func)  
        sweep[spending] = calc_total_infected(results)  
  
    return sweep
```

Here's how we run it.

```
In [31]: spending_array = linspace(0, 1200, 20)  
infected_sweep = sweep_hand_washing(spending_array)
```

```
Out[31]: values
```

	values
<b>0.000000</b>	0.466770
<b>63.157895</b>	0.465418

<b>1200.000000</b>	0.187596

And here's what it looks like.

```
In [32]: plot(infected_sweep)

decorate(xlabel='Hand-washing campaign spending (USD)',
         ylabel='Total fraction infected',
         title='Effect of hand washing on total infections',
         legend=False)

savefig('figs/chap12-fig03.pdf')
```

Now let's put it all together to make some public health spending decisions.

## Optimization

Suppose we have \$1200 to spend on any combination of vaccines and a hand-washing campaign.

```
In [33]: num_students = 90
budget = 1200
price_per_dose = 100
max_doses = int(budget / price_per_dose)
dose_array = linrange(max_doses, endpoint=True)
max_doses
```

```
Out[33]: 12
```

We can sweep through a range of doses from, 0 to `max_doses`, model the effects of immunization and the hand-washing campaign, and run simulations.

For each scenario, we compute the fraction of students who get sick.

```
In [34]: for doses in dose_array:
    fraction = doses / num_students
    spending = budget - doses * price_per_dose

    system = make_system(beta, gamma)
    add_immunization(system, fraction)
    add_hand_washing(system, spending)

    results = run_simulation(system, update_func)
    print(doses, system.init.S, system.beta, calc_total_infected(results))
```

```

12 0.8555555555555556 0.3328871432717143 0.25279694563572175
```

The following function wraps that loop and stores the results in a `Sweep` object.

```
In [35]: def sweep_doses(dose_array):
    """Runs simulations with different doses and campaign spending.

    dose_array: range of values for number of vaccinations

    return: Sweep object with total number of infections
    """
    sweep = SweepSeries()

    for doses in dose_array:
        fraction = doses / num_students
        spending = budget - doses * price_per_dose

        system = make_system(beta, gamma)
        add_immunization(system, fraction)
```

```
    add_hand_washing(system, spending)

    results = run_simulation(system, update_func)
    sweep[doses] = calc_total_infected(results)

return sweep
```

Now we can compute the number of infected students for each possible allocation of the budget.

```
In [36]: infected_sweep = sweep_doses(dose_array)
```

```
Out[36]: values
```

	values
0	0.187596
1	0.174581
2	0.162910
3	0.153508
4	0.148565
5	0.152946
6	0.174964
7	0.217343
8	0.259071
9	0.278403
10	0.277915
11	0.267357
12	0.252797

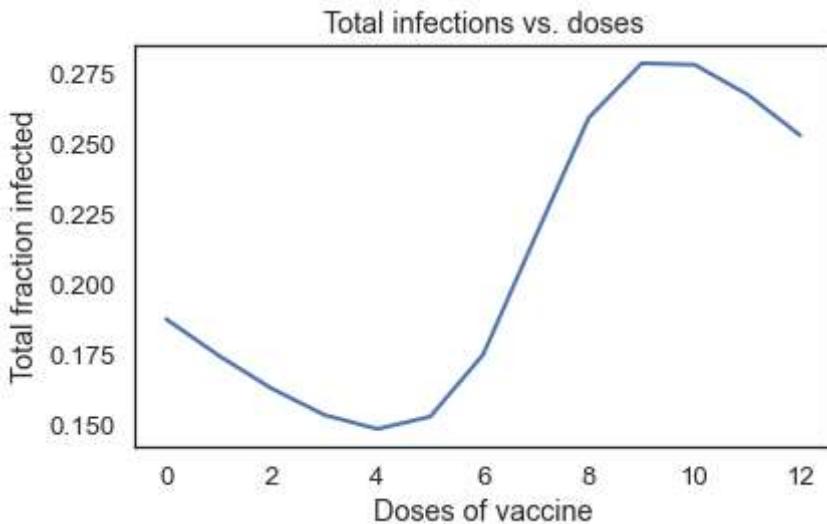

And plot the results.

```
In [37]: plot(infected_sweep)

decorate(xlabel='Doses of vaccine',
         ylabel='Total fraction infected',
         title='Total infections vs. doses',
         legend=False)

savefig('figs/chap12-fig04.pdf')
```

Saving figure to file figs/chap12-fig04.pdf

## Exercises

**Exercise:** Suppose the price of the vaccine drops to \$50 per dose. How does that affect the optimal allocation of the spending?

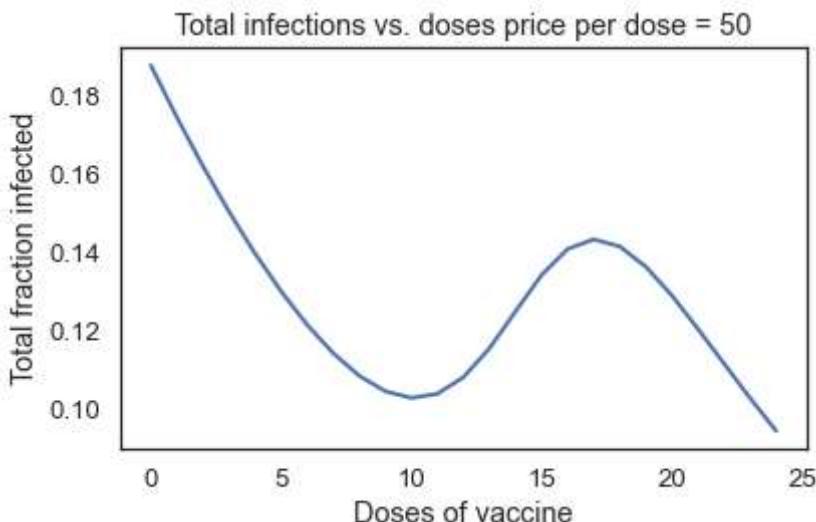

```
In [38]: # Solution goes here

num_students = 90
budget = 1200
price_per_dose = 50
max_doses = int(budget / price_per_dose)
dose_array = linrange(max_doses, endpoint=True)

infected_sweep = sweep_doses(dose_array)

plot(infected_sweep)

decorate(xlabel='Doses of vaccine',
        ylabel='Total fraction infected',
        title='Total infections vs. doses price per dose = 50',
        legend=False)
```

**Exercise:** Suppose we have the option to quarantine infected students. For example, a student who

feels ill might be moved to an infirmary, or a private dorm room, until they are no longer infectious.

How might you incorporate the effect of quarantine in the SIR model?

In [39]: # Solution goes here

```
def quarantine(system, fraction):
    """Introduces quarantine into the SIR model.

    system: System object.

    fraction: The fraction of students under quarantine.

    return: System object with quarantine.
    """

    days_quarantine = 1
    days_without_quarantine = 4
    tr = days_without_quarantine - fraction * (days_quarantine - days_without_quarantine)
    system.gamma = 1 / tr

    return system

# Call the function.
quarantine(system, fraction)

system3 = make_system(beta, gamma)
quarantine(system3, 0.10) #fraction of infected students quarantined
results3 = run_simulation(system3, update_func)
calc_total_infected(results3)

plot(results3.S, '-', label='quarantine')

decorate(xlabel='Time (days)',
         ylabel='Fraction susceptible',
         title='Effect of 10% quarantine',
         legend=False)
```

In [40]: # Solution goes here

```

def quarantine(system, fraction):
    """Introduces quarantine into the SIR model.

    system: System object.

    fraction: The fraction of students under quarantine.

    return: System object with quarantine.
    """

    days_quarantine = 1
    days_without_quarantine = 4
    tr = days_without_quarantine - fraction * (days_quarantine - days_without_quarantine)
    system.gamma = 1 / tr

    return system

# Call the function.
quarantine(system, fraction)

system3 = make_system(beta, gamma)
quarantine(system3, 0.70) #fraction of infected students quarantined
results3 = run_simulation(system3, update_func)
calc_total_infected(results3)

plot(results3.S, '--', label='quarantine')

decorate(xlabel='Time (days)',
         ylabel='Fraction susceptible',
         title='Effect of 70% quarantine',
         legend=False)

```
